A very simple document on the Metabolic Theory of Ecology

Vitor Ferreira

Abstract

This paper elaborates on the principles of chemistry, physics and biology drawn into a fundamental equation that links indididuals to higher orders of organization.

1 Introduction

Metabolism is the rate that organisms uptake and allocate resources for their growth, survival and reproduction.

2 Materials & Methods

Accounting for the effects of body size and temperature on individual metabolic rates, the formula can be provided as follows:

$$I = i_0 * M^{\frac{3}{4}} e^{\frac{-E}{kT}} \tag{1}$$

where, i_0 is the normalization constant, M is the body size, E is the activation energy, k the Boltzmann's constant and T is the absolute temperature in K.

The allometric scaling of this phenomenum applies across several orders of magnitude and levels of organization [1].
